Configuration Manual

Souvick Pradhan
Student ID: 23329882

1 System Overview & Environment Requirements

1.1 Purpose of This Document

This manual explains how the whole system is meant to be set up so the user can get everything running without guessing too much. The setup includes Controller, MongoDB, Relay, Socket Server, Connector, and Client. All of these pieces talk to each other to form a simple Zero Trust-style remote access system. (Rose, 2020).

1.2 Host System Requirements

The deployment was carried out using lightweight Ubuntu 22.04 virtual machines. These VMs were hosted on a Windows machine with the following basic hardware:

- CPU: **AMD Ryzen 5 4600H (6 cores)**
- RAM: **6 GB allocated to Controller VM**, and **2 GB** for each of the smaller services
- Disk: **50 GB** for the Controller VM
- OS: **Ubuntu 22.04 LTS** used across all VMs
- Virtualization: **VirtualBox**

This setup is enough for running MongoDB, the Controller UI, and the three Python services without too much slowdown.

1.3 Virtual Machine Allocation

VM	CPU	RAM	Disk	OS
Controller	2 cores	6 GB	50 GB	Ubuntu 22.04
PLC Machine	2 cores	4 GB	25 GB	Ubuntu 22.04
Relay	1 core	2 GB	10 GB	Ubuntu 22.04
Socket Server	1 core	2 GB	10 GB	Ubuntu 22.04
Connector (OT gateway)	1 core	2 GB	10 GB	Ubuntu 22.04
Client VM	1 core	2 GB	10 GB	Ubuntu 22.04

The Controller VM needs the most resources because it runs Node.js and MongoDB. The remaining machines only handle networking traffic or token verification, so they remain light.

1.4 Required Software & Dependencies

Controller (Node.js)

Packages from package. Json (summarized):

- next, react, react-dom: UI rendering.
- mongoose: talking to MongoDB.
- next-auth: login + JWT/session handling
- socket.io-client: real-time updates
- axios / fetch: API communication
- tailwindcss: UI styling
- typescript + @types: safer typing

```
Final > Controller > {} package.json > {} dependencies

34     "tailwindcss": "^3.3.0",
35     "typescript": "^5"
36   }
37 }
```

Python Runtime (Relay, Socket Server, Client, Connector) Main Python libraries:

- pymongo: MongoDB queries
- python-socketio: real-time communication

- python-dotenv: reading .env files (when used)
- cryptography / pyjwt: decoding and verifying JWT tokens.
- requests: talking to the Controller.
- built-in socket, asyncio: for UDP tunnelling and async loops.

1.5 Ports Used in the System

Component	Port	Protocol
Controller	3000	HTTP
MongoDB	27017	TCP
Socket Server	5001	WebSocket/HTTP
Relay	9090	UDP
Connector	(dynamic)	UDP
Client	(dynamic)	UDP

2 Configuration Steps

2.1 MongoDB Setup

MongoDB is installed on the Controller VM. No initial setup is required because the Controller will automatically create collections on first run. (MongoDB, 2024) Connection string:

`mongodb://localhost:27017/ztna`

2.2 Controller Configuration (Next.js)

To start with the Controller UI, the following steps are carried out:

1. Install Node.js dependencies.
2. npm install.
3. Create the .env.local file with keys, secrets and URLs.
4. Start the Controller using:
5. npm run dev.
6. Open the web browser and visit:
7. <http://localhost:3000>

Once everything loads, the login screen should appear. (Vercel, 2024)

```
PS E:\Final\Final\Controller> npm run dev
```

```
> controller@0.1.0 dev
> next dev
```

```
▲ Next.js 14.0.3
```

```
- Local:      http://localhost:3000
- Environments: .env.local
```

Attention: Next.js now collects completely anonymous telemetry regarding usage.

This information is used to shape Next.js' roadmap and prioritize features.

You can learn more, including how to opt-out if you'd not like to participate in this anonymous program, by visiting the following URL:

<https://nextjs.org/telemetry>

```

2.3 Creating Networks, Connectors, Resources, Users, and Groups

These steps were performed through the Controller UI, which was connected to MongoDB (verified through both testing docs and SS folder images:).

2.3.1 Network Setup

- Open **Networks** then go to **Remote Network**
- Create the network (e.g., *simulation network*)
- Confirm that it appears in the list.

2.3.2 Connector Setup

- Go to **Connectors**
- Add a new connector (*Simulation-gateway*)
- Status should be set to **Enabled**.

Connector Management

Manage and track connector information

Connectors

Networks

simulation network present at Test location

S

Simulation-gateway
IP: 100.64.0.1

2.3.3 Resource Setup

- Go to **Resources**
- Add a PLC or test IP, for example:
 - Name: PLC-1-Test
 - IP: 192.168.10.10
 - Network: *simulation network*

Resources

1
Resources

Networks

simulation network present at Test location

P

PLC-test
IP: 192.168.10.10
Alias:

2.3.4 User Setup

- Create a vendor user (e.g. vendor@test.com)
- The default admin user remains admin@ztna.com

2.3.5 Groups (Optional)

- The Controller UI shows groups.
- A group may be associated with the user if needed.

2.3.6 Creating Policies

- Go to **Policies**
- Create a policy linking **Vendor to PLC-1-Test**
- This determines which resource the client can access.

3 Environment Configuration

3.1 Controller (.env.local)

Purpose:

- Stores all secrets used by Next AUTH
- Stores the MongoDB URI
- Contains the Controller's private key (JWT signing key) (Jones, 2015)
- Holds Relay and Socket Server addresses.
- After filling in the .env.local, the Controller can be launched normally with:

npm run dev

```
page.tsx  .env.local  x  JS  env.js  .env  x.txt  package.json

Final > Controller > .env.local
1 NEXTAUTH_SECRET=this_key_is_secret_ket_For33A44Controllerkshifh
2 NEXTAUTH_URL=http://localhost:3000
3 #MONGODB=mongodb+srv://user:password1234@cluster0.dt9df61.mongodb.net/?appName=Cluster0

13 REFRESH_EXPIRY=30
14
15 # Relay Configuration
16 RELAY_ADDR=192.168.121.101:9089
17 RELAY_PORT=9090
18 SOCKET_ADDR=http://localhost:5001
```

3.2 Relay

Purpose:

- Holds the Controller public key.
- Stores the Controller URL
- Allows the Relay port to be set from an .env file if needed.

How to Run Relay with .env:

- Place .env inside relay/app/
- At the top of server.py, add:

```
from dotenv import load_dotenv
load_dotenv()
```

- Replace hard-coded values in the Relay code with:

```
os.getenv("PUBLIC_KEY") os.getenv("CONTROLLER_URL")
int(os.getenv("RELAY_PORT"))
```

- Start the Relay:

```
python server.py
```

Now the Relay will load its values from the .env file at startup.

```
Final > relay > app > .env.sample

7 1QIDAQAB|
8 CONTROLLER_URL=http://localhost:3000
9 RELAY_PORT=9090
10
```

4 Connector Deployment (Dockerised)

The connector is provided as a Dockerised service. Users do not need to run Python files or install dependencies manually. Instead, the connector container is started directly using Docker. (Docker, 2024)

Before running the command, the Controller UI must be used to generate a Connector Access Token and Refresh Token. Once those are available, the connector can be deployed by running:

```
PS E:\Final\Final\connector> docker build -t ztna-connector-image .
[+] Building 3.8s (1/2)
=> [internal] load build definition from Dockerfile
=> transferring dockerfile: 1.17kB
=> [internal] load metadata for docker.io/library/ubuntu:20.04
```

Here is the command the user has to run:

```
docker run -d \
--name ztna-connector \
-e ACCESS_TOKEN=<paste-your-connector-access-token-here> \
-e REFRESH_TOKEN=<paste-your-connector-refresh-token-here> \
-e RELAY_IP=<relay-ip-address> \
-e RELAY_PORT=9090 \
-e SOCKET_SERVER_ADDR=http://<socket-server-ip>:5001 \ connector-image: latest
```

After running this command, the container will start in the background. You can check if it's running by typing:
docker ps

5 Client Configuration (client.py & GetToken.py)

The Client service uses two Python files for authentication and tunnel setup.

5.1 Token Retrieval (GetToken.py)

GetToken.py opens a tiny local HTTP server to receive authentication tokens from the

Controller using PKCE. (Sakimura, 2015) Key

behaviors:

- Listens on **port 8080** for /callback
- Generates PKCE values (code_challenge, code_verifier)
- Prints a login URL such as:
- `http://localhost:3000/profile?challenge=<value>`
- After the user opens this URL and logs in, the script receives:

- Access Token
- Refresh Token
- Code Verifier

The script prints them in the terminal for client use (Hardt, 2012).

User Flow:

1. Ensure Controller is running.
2. Run: `python GetToken.py`
3. Open the printed URL in the browser.
4. Tokens appear in the terminal.

```
Final > client > GetToken.py > RequestHandler > do_OPTIONS
1 from http.server import BaseHTTPRequestHandler, HTTPServer
2 from json import loads
3 import secrets
4 from hashlib import sha256
5 from base64 import urlsafe_b64encode
6
7 access_token = None
8 refresh_token = None
9
10 def generate_pkce():
11     code_verifier = secrets.token_urlsafe(96)[:128]
12     code_challenge = urlsafe_b64encode(sha256(code_verifier.encode('ascii')).digest()).decode('ascii')[:-1]
13     return code_verifier, code_challenge
14
15 class RequestHandler(BaseHTTPRequestHandler):
16     def do_OPTIONS(self):
17         self.send_response(200)
18         self.send_header('Access-Control-Allow-Origin', '')
19         self.send_header('Access-Control-Allow-Methods', 'POST, OPTIONS')
20         self.send_header('Access-Control-Allow-Headers', 'Accept, Content-Type, Content-Length, Accept-Encoding, X-CSRF-Token, Authorization')
21         self.end_headers()
22
23     def do_POST(self):
24         global access_token, refresh_token
25         if not self.path.endswith('/callback'):
26             self.send_response(404)
27             self.end_headers()
28             return
29
30         try:
31             content_length = int(self.headers['Content-Length'])
32             post_data = self.rfile.read(content_length).decode('utf-8')
33             data = loads(post_data)
34
35             access_token = data.get('accessToken', None)
36             refresh_token = data.get('refreshToken', None)
37
38             self.send_response(200)
39             self.send_header('Access-Control-Allow-Origin', '') # Allow from all origins
40             self.send_header('Access-Control-Allow-Methods', 'POST') # Allow only POST method
41             self.send_header('Access-Control-Allow-Headers', 'Content-Type') # Allow only Content-Type header
42             self.send_header('Content-type', 'text/plain')
43
44 PS E:\Final\Final\client> python .\GetToken.py
Starting token retrieval...
Goto http://localhost:3000/profile?challenge=dhvDm1VdLKp8oyhwjFCPRCQq6E30wBilneC1_KXPYUY
□
```

Authentication successful

Redirecting to Desktop Application

5.2 Client Agent (client.py)

client.py is the component that builds the secure tunnel, creates the TUN interface and forwards packets.

Important internal settings:

- At the bottom, it calls:
- `access_token, refresh_token, code_verifier = get_token()`
- It decodes the JWT to get the client ID • Key network settings appear near the top:
- `relay_address = ('127.0.0.1', 9090)`
- `socket_server_address = 'http://localhost:5001'`
- It creates and removes the virtual interface (tun0)
- It adds and deletes routes to PLC resources.
- It performs a handshake with the Relay using the Relay's public key.
- Finally, it forwards encrypted UDP packets.

The main configuration points the user needs to adjust are:

1. `relay_address`: the IP and port of the Relay
2. `socket_server_address`: WebSocket control-plane server
3. The fact that token collection is done automatically by calling `get_token()`

```
PS E:\Final\Final\client> python client.py
Starting token retrieval...
Goto http://localhost:3000/profile?challenge=AMG7GKZrt1RDbEF_pyk2z-C2mzH3Vk7P-JZB01A9euQ
█

6 Conclusion

This setup guide describes the manner in which every component of the system should be configured to ensure that the entire Zero Trust workflow can operate without issues. MongoDB, Relay, Socket Server, Connector and Client relied on one another, and therefore, the manual was dedicated to demonstrating where the environment files will reside, how the services should be launched, and what the user is supposed to press or execute. The testing images and installation instructions indicated that the Controller was connected correctly with MongoDB, new networks and connectors were visible accordingly, and the client was able to authenticate with the help of PKCE and then be assigned its permitted routes. Although the system is composed of a number of small elements, the elements are all predictable in nature, and once the environment variables and the tokens are placed in their respective locations, the services function as expected. All in all, this should provide a simple method of enabling someone to replicate the setup and test the Zero Trust behaviour in a small laboratory setup.
